TITLE: Eliminating the Causes of Blistering in Hot-dip Galvanizing
(Ustraneniye prichin vozniknoveniya puzyrey pri goryachem
otsinkovanii)

PERIODICAL: Tr. Khar'kovsk. politekhn. in-ta, 1957, Vol 13, pp 69-72

ABSTRACT: An investigation is conducted into various methods of electro-chemical etching of hot-dip articles to eliminate blistering, the cause of which is related to the high internal pressure of the hydrogen formed on etching, and diffusing into the depth of the metal. A 20% H_2SO_4 solution at 45°C and 2 hours holding time were conditions of the investigation. It was established that blisters do not form on anodic etching and A-C etching. The absence of blisters in the latter case is related to the fact that when A-C passes through the electrodes, an accumulation of atomic H sufficient to cause diffusion of the H in the metal cannot build up. It is established that A-C etching is the best. When the objects are in contact with Cu and Pt, the amount of H liberated on them diminishes. However, even a small amount of H

Card 1/2

Eliminating the Causes of Blistering in Hot-dip Galvanizing

liberated in this case suffices for blister formation (owing to the difference effect). The methods may be arranged in series in terms of diminishing etching speed: cathodic etching, A-C etching, anodic and chemical etching.

TITLE: Contributions to the theory of antiferromagnetic resonance in metals

SOURCE: Zh eksper i teor fiz, v. 51, no. 6, 1966, 1703-1711

TOPIC TAGS: antiferromagnetism, ferromagnetic resonance, electric conductivity, plasma wave, spin wave

ABSTRACT: The authors explain the role played by plasma effects in antiferromagnetic resonance. The analysis is restricted to uniaxial antiferromagnets with positive anisotropy constant. The role of spatial dispersion in the variation of the surface impedance is first determined near the antiferromagnetic resonance frequencies. This is followed by consideration of the influence of the magnetic field on the electric conductivity, under the assumption that the resonance frequencies lie in the range where helicon waves exist. It is shown how the nature of the ground state is reflected in the properties of the electromagnetic waves, and that in the case of a comparatively weak magnetic field, undamped waves can be propagated in an antiferromagnetic metal. One of these is the supplementary wave due to spatial dispersion. The frequency dependence of the surface impedance exhibits singularities, which are explained. Couple spin-helicon waves are shown to propagate in an antiferromagnetic

TITLE: Investigation of the Thermal Behaviour of Intermediate Ladles

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Chernaya metallurgiya,
1960, No. 10, pp. 58 - 66

TEXT: The investigation had been carried out to determine the heat losses from metal in intermediate ladles. Small ladles at the New-Tula Metallurgical Plant and large at the imeni Dzerzhinskiy Plant were studied. The small ladles were heated with blast furnace gas burning in an oxygen jet, and the large with coke gas; chromel-alumel and platinum-rhodium-platinum thermocouples were inserted into the ladle linings as shown in Fig. 1 and 2; the metal temperature in ladles was measured with platinum-rhodium-platinum and tungsten-molybdenum immersion thermocouples; indicating and recording galvanometers and an -09 (EPP-09) writing potentiometer were used. The duration of teeming was 20 - 26 min at the New Tula Plant (NTMZ) and 80 - 120 min at the imeni Dzerzhinskiy Plant. A graph gives the measurement results in a large ladle (Fig. 3) - there is practically no

Card 1/3

A161/A030

Investigation of the Thermal Behaviour of Intermediate Ladles

heat gradient inside the intermediate ladle, apparently due to a feed of fresh hot metal from the main ladle. The lining temperature on the surface quickly reached the metal temperature; it dropped nearly 180°C during 5 min after the gas heating was stopped before teeming. E.A. Iodko and L.I. Krupman calculated the heating of lining to determine the effect of separate factors. The "working" layer of lining was stated to be 20 - 30 mm in small ladles, and 60 - 80 mm in large, which is less or equal to the usual fireclay lining depth and shows that additional heat insulation of the ladle casings is superfluous. The calculation is included in the article. The formula (13) determines the effect of the heat conductivity of the ladle lining on the drop in metal temperature in the ladle and shows that the relation is in direct proportion. The heat loss by radiation had not been considered. It was concluded that the heat conductivity in fireclay brick layers nearest to the contact surface with metal drops in the teeming process and the first metal portions in the intermediate ladle are cooled by the lining surface, whilst the heat gradient inside the lining has practically no influence. It is therefore proper to heat the lining at a high temperature on the surface ignoring high temperature gradients in the lining below the surface, and not to stop heating the ladle before the start of teeming. Cooling of the first metal

TITLE: Some Drawbacks of Control- and Measuring Instruments¹⁴

PERIODICAL: Priborostroyeniye, 1960, Nr 2, p 21 (USSR)

ABSTRACT: The following drawbacks of instruments are enumerated:
1) In thermoelectric power plants, lamps of 220 v and 25 w are used for the circuits of light - sound signaling. Switches designed for 50 ma and 110 v are frequently used for such systems. A frequently used pressure gauge is designed only for 10 ma as a maximum. There is an unlimited number of examples which illustrate the difficulties to be mastered in fitting the contact elements into the signaling circuit. 2) The greater part of instruments is designed for a voltage of 220 v, and those instruments which are to be fed with a voltage of 127 v are difficult to fit into large circuits. 3) The author first notes that measuring instruments developed by various factories are frequently graduated counterclockwise, which fact may lead to errors in the operation of large switchboards. Furthermore, several firms use for light signals different colors for the same purpose.

Nauchno-tekhnicheskiye iznaniya v massy: sbornik materialov
nauchnoy massovoy biblioteki (Scientific and Technical
Knowledge for Everyone; Collection of Materials for the
Aids of Public Libraries) Moscow, 1958. 196 p. Errata
slip inserted. 15,000 copies printed.

Compilers: O. S. Multanovskaya and V. V. Koyman; Ed. I. D.
Yagodina. Candidate of Pedagogical Sciences; Tech. Ed. I.
L. M. Kholevskaya.

PURPOSE: This book is intended for librarians.

COVERAGE: This collection of articles reviews popular
scientific and technical literature as aid public library
workers in disseminating science information to the reading
public. The role and significance of principal industries

in the technological development of the USSR are covered.
The last two articles describe the experience of individual
libraries in promoting popular-science books. The appendix
gives a list of bibliographic aids for popular-science
literature. No personalities are mentioned.

ACC NR: AR6027135

SOURCE CODE: UR/0272/66/000/004/0164/0165

AUTHOR: Yankelevich, Yu. B.

TITLE: A scintillation spectrometer for studying energy and angular distributions of X ray emission behind various absorbers

SOURCE: Ref. zh. Metrologiya i izmeritel'naya tekhnika, Abs. 4.32.1205

REF SOURCE: Izv. Tomskogo politekhn. in-ta, v. 138, 1965, 49-52

TOPIC TAGS: scintillation spectrometer, X ray emission, X ray measurement

ABSTRACT: A scintillation γ -spectrometer consisting of an NaI(Tl) crystal, an FEU-24 photoamplifier, a preamplifier and an AI-100 amplitude analyzer is described. Resolution of the spectrometer with respect to energy was 8.5% for 660-keV γ -quanta and improved up to 7% for 1.25-MeV γ -quanta. The spectrometer was used to measure emission spectra at the output of an industrial X-ray device of the RUP-200 type and energy spectra of the X-ray emission behind various absorbers (steel, aluminum, plastics, etc.) at various angles θ ($0^\circ \leq \theta \leq 180^\circ$). A preliminary analysis of the results obtained has confirmed the possibility of radiography of materials by means of the Compton and coherently diffused at various angles X-ray emission. TITLE: The Heat Conductivity of Electrolytic Alkalies (Teplo-
provodnost' elektroliticheskikh shchelokov)

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy - Energetika,
1958, Nr 9, pp 56-60 (USSR)

ABSTRACT: Solutions are investigated that correspond to specific
stages in technological production. Weak electrolytes
(100-120 g/l NaOH, 175-200 g/l NaCl and low content of
Na₂SO₄) after electrolysis: Average electrolytes, after
the first stage of their concentration: Strong electro-
lytes, after evaporation is completed. The paper des-
cribes the test equipment for determining the heat con-
ductivity factor of these solutions. The method is
identical to that for hard bodies. The equipment must
be designed to guard against convection currents, which
may completely distort the results. Consequently the
thickness of the fluid layer is reduced to a minimum

Card 1/3

SOV/143-58-9-8/18

The Heat Conductivity of Electrolytic Alkalies

and temperature jumps in the fluid layer decrease. The idea of this method is that by passing a stream of heat in turn through a layer of test fluid and a layer of standard fluid, a temperature jumps are set up inversely proportional to the heat conductivity factor. The authors used the comparative surface layer method of A.F.Kapustinskiy and I.I.Ruzavin. The advantages of this method are: 1) There is no danger of a convection current, 2) Measurements for determining the stream of heat that passes through the test layer are avoided. 3) All measurements are reduced to precise determination of the temperature differences between the plates. The paper then describes the equipment and the test results. The experiments were carried out with three combinations of caustic soda solutions at temperatures of 40 - 90°C using distilled water as the standard fluid. The three solutions studied corresponded approximately to the three of weak, average and strong electrolytic alkalies NaOH, NaCl and Y2O. The heat conductivity of the test solutions

Card 2/3

SOV/14358-9-8/18

• The Heat Conductivity of Electrolytic Alkalies

increases with a rise in temperature and follows the change in the heat-conductivity of the water. With an increase in NaOH concentration, the solution's conductivity rises. It is less than the heat conductivity of water at low concentrations and greater than it at large ones. This is explained by the varied influence of the constituent components on the heat-conductivity of the solution. There are 1 table, 1 diagram, 1 graph and 3 Soviet references.

TITLE: Effect of an Impulse Flow of High Temperature Gases on the Surface Layer of Steel (Vliyaniye impul'snogo potoka gazov vysokoy temperatury na poverkhnostnyy sloj stali)

PERIODICAL: Dopovidi Akademii Nauk Ukrain's'koi RSR, 1957, Nr 5, pp. 480-484 (USSR)

ABSTRACT: The author carried out experiments with impulse flow of high-temperature gases. In one of the experiments 2.3 g of smokeless powder was placed into a combustion chamber with samples of steel of the "40 X" type. The burning of the powder which lasted 0.02 sec produced a gas pressure of 2,800 to 4,100 atm and a temperature of 2,500°C. The flow of this gas polished the surface of the steel sample under investigation and reduced its micro unevenness from 4.2 microns to 0.3 microns. The impulse flow of high-temperature gases produces also structural changes in metals. An experiment with Armco-iron resulted in the formation of a light surface layer of 80 to 120 microns. Samples of "40X" steel subjected to an impulse flow of gases also showed the formation of white layers of 50 to 60 micron thick. The basic part of this layer has a high microhardness of 750 to 775 kg/sq mm; its structure is austen-

Card 1/2

21-5-14/26

Effect of an Impulse Flow of High Temperature Gases on the Surface Layer of Steel

ite-martensite. Thus the impulse flow of high-temperature gases hardened the surface steel layer, and the hardness obtained in this way exceeds that produced under conventional conditions. The experiments have shown that it is possible to obtain the hardened layer of various thickness and structure and the surface of a required degree of evenness by means of varying the duration of burning, pressure and temperature of the gases and other conditions of gas flow. The author draws a conclusion that this method of impulse gas blowing can be applied as a technological process of thermo-mechanical treatment of small orifices where other method present difficulties. The article contains 2 photos, 2 graphs and 2 Slavic references.

of temperature and pressure shocks

SOURCE: Soveshchaniye po voprosam teorii sukhogo treniya i obra-
zovaniya chastits iznosa pri sukhom trenii. Riga, 1959,
97-105

TEXT: The authors investigated the crystal structure and composi-
tion of "white" layers formed on steel by high pressures and tem-
peratures. For x-ray diffraction work an instrument YPC-50 W (URS-
501) was used; electron-microscopic and spectroscopic techniques
were also employed. The authors studied the effects of (1) grind-
ing roller-bearing parts with an abrasive disc rotating at various
speeds and subjected to various loads; (2) normal working condi-
tions on transmission gear teeth from a PA3-63 (GAZ-63) automobile,
and (3) hot-gas blasts (1200 kg/cm² for 0.0025 sec) on steels 45

and γ_{10} (U10). In all three cases similar changes occurred: (1) Well above their critical temperatures both austenite and martensite were formed in hypereutectoid steel and martensite only in hypoeutectoid steel; (2) austenite, martensite and ferrite were formed in all steels just above the lower critical temperature; (3) below the critical temperature ferrite was formed, by thermoplastic annealing, in all steels; (4) austenite, martensite and ferrite formed in these processes differed considerably in carbon content and lattice parameters from those obtained by the usual heat treatments. There are 9 figures.

TITLE: On the nature of "white" layers

SOURCE: Soveshchaniye po voprosam teorii sukhogo treniya i obrazovaniya chstits iznosa pri sukhom trenii. Riga, 1959, 107-119

TEXT: The author investigated formation, composition and structure of "white" layers at the surface of steel and cast iron. White layers have been studied by N. N. Davidenkov, B. D. Grozin, L. S. Palatnik, I. M. Lyubarkiy, B. I. Kostetskiy, A. D. Kuritsyna, G. M. Zamoruyev and others. There is as yet no generally accepted view on their formation and structure. The present author used electron-microscopic, spectroscopic and x-ray diffraction techniques to study white layers. In optical work a quartz-glass spectrograph KCA-1 (KSA-1) was used and spectra were excited by a high-frequency spark. For x-ray diffraction an instrument YPC-50H (URS-50I), with an ionization counter, was employed. The materials

investigated were: (1) Cast-iron piston rings from a two-stroke diesel engine AK 30/40 (DK 30/40) after 50 hours operation; (2) AW-62MP (ASH-62IR) type aviation-engine piston rings made of steels 38XMMOA, X 12M (38KhMYuA, Kh12M) and of cast irons ЛЛ4-1, XTB (PLCh-1, KhTV), subjected to 30 - 40 hours operation; (3) steel nozzles subjected to blasts of hot gases from combustion of gunpowder; (4) 40X (40Kh) steel plates subjected to hot-gas blasts produced by burning smokeless gunpowder. The results obtained by the author and by other workers studying friction, mechanical impact, electric-spark erosion, grinding, cutting etc., led to the following conclusions about white layers of steel and iron alloys: (1) These layers should be studied using simultaneously several physical methods in order to obtain the fullest information; (2) they may consist of austenite, martensite, ferrite and other phases, and their actual structure depends very strongly on the physico-chemical conditions, under which they are formed; (3) they are formed mostly under the conditions of rapid heating and cooling at temperatures above the critical; (4) they differ consider-
